Generalised Linear Models: Logistic regression

Q: Survival of passengers on the Titanic ~ Class

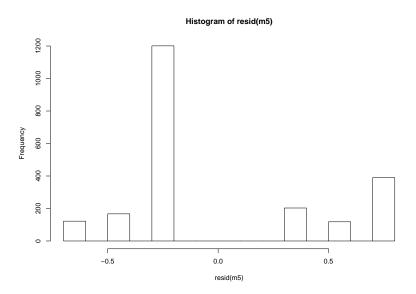

Read titanic_long.csv dataset.

```
class age sex survived
1 first adult male 1
2 first adult male 1
3 first adult male 1
4 first adult male 1
5 first adult male 1
6 first adult male 1
```

Let's fit linear model:

Weird residuals!

What if your residuals are clearly non-normal? | And variance not constant (heteroscedasticity)?

▶ Binary variables (0/1)

What if your residuals are clearly non-normal? | And variance not constant (heteroscedasticity)?

The modelling process

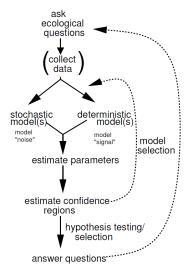

Figure 1.5 Flow of the modeling process.

Figure 1:

Bernouilli - Binomial distribution (Logistic regression)

► Response variable: Yes/No (e.g. survival, sex, presence/absence)

$$logit(p) = ln\left(\frac{p}{1-p}\right)$$

Then

$$Pr(alive) = a + bx$$
 $logit(Pr(alive)) = a + bx$
 $Pr(alive) = invlogit(a + bx) = \frac{e^{a+bx}}{1 + e^{a+bx}}$

Bernouilli - Binomial distribution (Logistic regression)

- ► Response variable: Yes/No (e.g. survival, sex, presence/absence)
- ▶ Link function: logit (others possible, see family).

$$logit(p) = ln\left(\frac{p}{1-p}\right)$$

Then

$$Pr(alive) = a + bx$$
 $logit(Pr(alive)) = a + bx$ $Pr(alive) = invlogit(a + bx) = \frac{e^{a+bx}}{1 + e^{a+bx}}$

How many passengers travelled in each class?

How many passengers travelled in each class?

```
tapply(titanic$survived, titanic$class, length)
```

```
crew first second third 885 325 285 706
```

How many passengers travelled in each class?

```
tapply(titanic$survived, titanic$class, length)
```

```
crew first second third 885 325 285 706
```

How many survived?

How many passengers travelled in each class?

```

crew first second third
885 325 285 706
```

How many survived?

```
tapply(titanic$survived, titanic$class, sum)
```

```
crew first second third 212 203 118 178
```

How many passengers travelled in each class?

```
tapply(titanic$survived, titanic$class, length)
```

```
crew first second third 885 325 285 706
```

How many survived?

```
tapply(titanic$survived, titanic$class, sum)
```

```
crew first second third 212 203 118 178
```

What proportion survived in each class?

```
as.numeric(tapply(titanic$survived, titanic$class, mean))
```

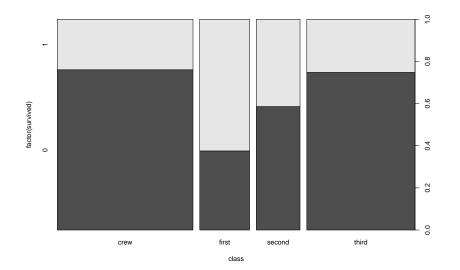

[1] 0.2395480 0.6246154 0.4140351 0.2521246

Passenger survival according to class

```
library(dplyr)
titanic %>%
 group_by(class, survived) %>%
 summarise(count = n())
# A tibble: 8 \times 3
# Groups: class [?]
  class survived count
 <fctr> <int> <int>
   crew
                   673
2
               1 212
 crew
3 first
               0 122
               1 203
 first
               0 167
5 second
               1 118
 second
  third
               0 528
                   178
  third
Or summarise(group by(titanic, class, survived), count =
n())
```

Or graphically...

```
plot(factor(survived) ~ class, data = titanic)
```

Fitting GLMs in R: glm

```
tit.glm <- glm(survived ~ class, data=titanic, family=binomial)</pre>
Call:
glm(formula = survived ~ class, family = binomial, data = titani
Deviance Residuals:
   Min 10 Median 30 Max
-1.3999 -0.7623 -0.7401 0.9702 1.6906
Coefficients:
          Estimate Std. Error z value Pr(>|z|)
classfirst 1.66434 0.13902 11.972 < 2e-16 ***
classsecond 0.80785 0.14375 5.620 1.91e-08 ***
classthird 0.06785 0.11711 0.579 0.562
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

(Dispersion parameter for binomial family taken to be 1)

Interpreting logistic regression output

Parameter estimates (logit-scale)

```
(Intercept) classfirst classsecond classthird -1.15515905 1.66434399 0.80784987 0.06784632
```

We need to back-transform: apply *inverse logit* Crew probability of survival:

```
plogis(coef(tit.glm)[1])
```

```
(Intercept)
0.239548
```

Looking at the data, the proportion of crew who survived is

```
[1] 0.239548
```

Q: Probability of survival for 1st class passengers?

```
plogis(coef(tit.glm)[1] + coef(tit.glm)[2])

(Intercept)
   0.6246154
```

Needs to add intercept (baseline) to the parameter estimate. Again this value matches the data:

```
sum(titanic$survived[titanic$class == "first"]) /
nrow(titanic[titanic$class == "first", ])
```

[1] 0.6246154

Model interpretation using effects package

```
library(effects)
allEffects(tit.glm)

model: survived ~ class

class effect
class
```

- 5. Examine models: summary
- Use plogis to apply back-transformation (invlogit) to parameter estimates (coef). Alternatively, use allEffects from effects package.
- Plot model: plot(allEffects(model)). Or use visreg.
- Examine residuals: use arm::binnedplot or DHARMa::simulateResiduals.

Plot first

```
plot(factor(survived) ~ sex, data = titanic)
```

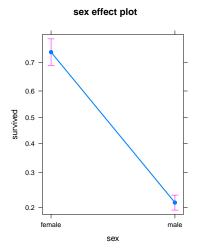

Fit model

```
tit.sex <- glm(survived ~ sex, data = titanic, family = binomial
Call:
glm(formula = survived ~ sex, family = binomial, data = titanic)
Deviance Residuals:
   Min 10 Median 30 Max
-1.6226 -0.6903 -0.6903 0.7901 1.7613
Coefficients:
           Estimate Std. Error z value Pr(>|z|)
(Intercept) 1.0044 0.1041 9.645 <2e-16 ***
sexmale -2.3172 0.1196 -19.376 <2e-16 ***
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
(Dispersion parameter for binomial family taken to be 1)
   Null deviance: 2769.5 on 2200 degrees of freedom
```

Effects

model: survived ~ sex
sex effect
sex
female male
0.7319149 0.2120162

Q: Did women have higher survival because

they travelled more in first class?

Let's look at the data

```
tapply
```

```
tapply(titanic\$survived, list(titanic\$class, titanic\$sex), sum)
```

```
female male
crew 20 192
first 141 62
second 93 25
third 90 88
```

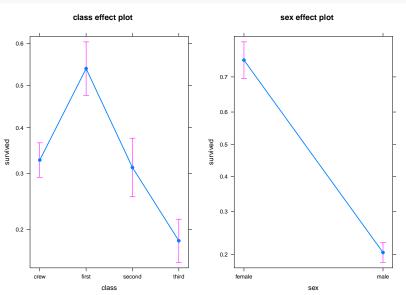

Mmmm...

Fit additive model with both factors

tit.sex.class <- glm(survived ~ class + sex, data = titanic, fam

Plot additive model

plot(allEffects(tit.sex.class))

Fit model with both factors (interactions)

```
glm(formula = survived ~ class * sex, family = binomial, data =
                 coef.est coef.se
(Intercept)
                1.90 0.62
classfirst
               1.67 0.80
classsecond
               0.07 0.69
classthird -2.06 0.64
sexmale
       -3.15 0.62
classfirst:sexmale -1.06 0.82
classsecond:sexmale -0.64 0.72
classthird:sexmale 1.74 0.65
 n = 2201, k = 8
 residual deviance = 2163.7, null deviance = 2769.5 (difference
```

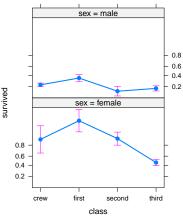

tit.sex.class <- glm(survived ~ class * sex, data = titanic, fam

Effects

model: survived ~ class * sex class*sex effect sex female class male crew 0.8695652 0.2227378 first 0.9724138 0.3444444 second 0.8773585 0.1396648 third 0.4591837 0.1725490

sex = male

class*sex effect plot

So, women had higher probability of survival than men, even within the same class.

Logistic regression for proportion data

Read Titanic data in different format

Read Titanic_prop.csv data.

```
X Class Sex Age No Yes
1 1 1st Female Adult 4 140
2 2 1st Female Child 0 1
3 3 1st Male Adult 118 57
4 4 1st Male Child 0 5
5 5 2nd Female Adult 13 80
6 6 2nd Female Child 0 13
```

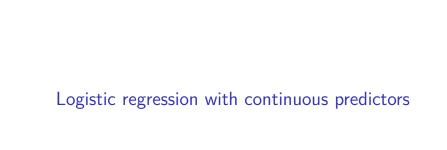

These are the same data, but summarized (see Freq variable).

Use cbind(n.success, n.failures) as response

```
prop.glm <- glm(cbind(Yes, No) ~ Class, data = tit.prop, family</pre>
Call:
glm(formula = cbind(Yes, No) ~ Class, family = binomial, data =
Deviance Residuals:
   Min 10 Median 30 Max
-9.6404 -0.2915 1.5698 5.0366 10.1516
Coefficients:
           Estimate Std. Error z value Pr(>|z|)
(Intercept) 0.5092 0.1146 4.445 8.79e-06 ***
Class2nd -0.8565 0.1661 -5.157 2.51e-07 ***
Class3rd -1.5965 0.1436 -11.114 < 2e-16 ***
ClassCrew -1.6643 0.1390 -11.972 < 2e-16 ***
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
(Dispersion parameter for binomial family taken to be 1)
```

Effects

```
model: cbind(Yes, No) ~ Class
Class effect
Class
     1st 2nd 3rd Crew
0.6246154 0.4140351 0.2521246 0.2395480
Compare with former model based on raw data:
model: survived ~ class
class effect
class
    crew
             first second third
0.2395480 0.6246154 0.4140351 0.2521246
Same results!
```

```

But standard errors (uncertainty) do!

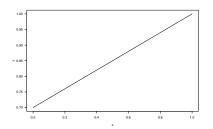

Plot model and data

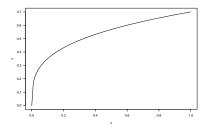

Whenever you fit logistic regression to **proportion** data, check family quasibinomial.

 $\label{eq:continuous} \begin{array}{l} y\sim x+z\\ \text{Really? Not everything has to be linear! Actually, it often is not.} \end{array}$ Think about shape of relationship. See chapter 3 in Bolker's book.

```
visreg(gdp.glm, ylab = "Mortality (logit scale)")
```
